# Proton transfer and tautomerism in 2-aminopurine–thymine and pyrrolocytosine–guanine base pairs

*Graham D. Bull and Katherine C. Thompson\**

Department of Biological Sciences and Institute of Structural and Molecular Biology, Birkbeck,  
University of London, Malet Street, Bloomsbury, London WC1E 7HX

**ABSTRACT:** Pyrrolocytosine (PC) and 2-aminopurine (2AP) are fluorescent nucleobase analogues of the DNA nucleobases cytosine and adenine, respectively, and form base pairs with guanine and thymine. Both fluorescent nucleobases are used extensively as probes for local structure in nucleic acids as the fluorescence properties of PC and 2AP are very sensitive to changes such as helix formation, although the reasons for this sensitivity are not clear. To address this question *ab initio* calculations have been used to calculate energies, at the MP2 and CIS level, of three different tautomer pairings of PC-G, and two of 2AP-T, which can potentially be interconverted by double proton transfer between the bases. Potential energy curves linking the different tautomer pairs have been calculated. For both PC-G and 2AP-T the most stable tautomer pair in the electronic ground state is that analogous to the natural C-G and A-T base pair. In the case of 2AP-T an alternative, stable, tautomer base pair was located in the first electronically excited state, however, it lies higher in energy than the tautomer pair analogous to A-T, making conversion to the alternative form

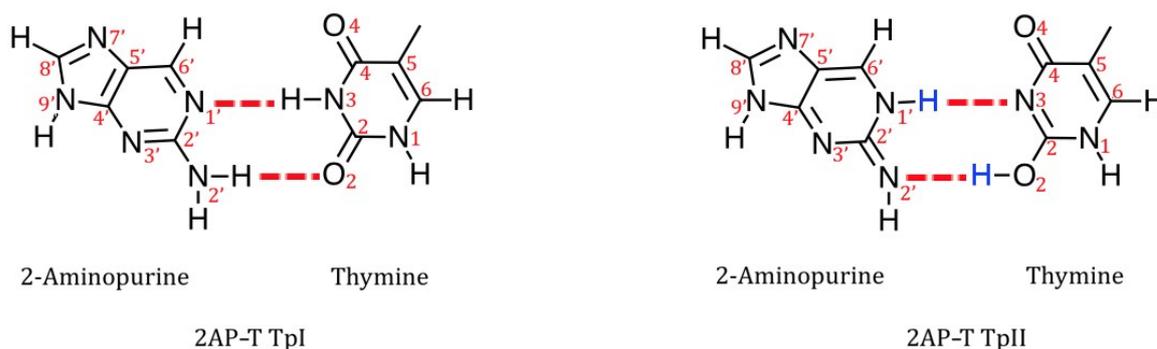

unlikely. In contrast, in the case of PC-G, an alternative tautomer base pair is found to be the most stable form in the first electronically excited state and this form is accessible following initial excitation from the ground state tautomer pair, thus suggesting an alternative deactivation route via double proton transfer may be possible when PC is involved in hydrogen bonding, such as occurs in helical conformations.

## INTRODUCTION

The photochemical properties of molecules very similar to the natural DNA nucleobases, including tautomers of the bases, are often significantly different to those of the DNA nucleobases themselves.<sup>1</sup> The natural DNA nucleobases all have low fluorescence quantum yield and very short fluorescent decay times.<sup>2</sup> Fluorescent nucleobase analogues are structurally similar to the natural bases, and are often able to form Watson-Crick like base pairs with the natural DNA bases, but have enhanced fluorescent properties i.e. higher quantum yields and longer lifetimes under prevailing physiological conditions (e.g. pH and salinity). Variations in intra or intermolecular interactions, solvent exposure or pH changes, may lead to changes in fluorescence properties such as emission intensity, excitation intensity, or fluorescence lifetime of the probe.<sup>3</sup> For this reason fluorescent nucleobase analogues are extensively used as tools by experimentalists working with nucleic acids to study a wide range of biochemical questions both *in vitro* and more recently *in vivo*, examples of which are given in the recent review article by Xu *et al.*<sup>4</sup> A better understanding of the underlying physical basis for the change in fluorescence properties in different environments is required so that existing nucleobase analogues may be used more effectively and novel ones designed.

As early as 1969, Ward *et al.* reported that 2-aminopurine, a structural isomer of the base adenine (6-aminopurine), was highly fluorescent and could be selectively excited in the presence of natural nucleobases.<sup>5</sup> When 2-aminopurine is substituted for adenine it leads to minimal perturbation to the structure of the nucleic acid as both bases are structurally similar and both can form a Watson-Crick-like base pair with thymine in DNA and uracil in RNA.<sup>6,7</sup> As an example of this lack of structural perturbation, the 2-aminopurine containing oligodeoxynucleotide d(CTGA[2AP]TTCAG)<sub>2</sub> is still recognized and cleaved by the enzyme *EcoRI* endonuclease.<sup>8</sup> 2-Aminopurine can also substitute for guanine and form a wobble structure with cytosine,<sup>6</sup> which is the basis of mutagenicity of

2-aminopurine.<sup>3,9</sup> The left hand structure in Scheme 1, labeled 2AP–T TpI, where Tp stands for Tautomer pair, shows the bonding of 2AP and thymine in an analogous manner to the Watson-Crick hydrogen bonding that occurs between adenine and thymine in DNA. The structure on the right hand side, labeled 2AP–T TpII, shows an alternative scheme where although the overall geometry is effectively unchanged, the hydrogen bonding is between different tautomers of both 2AP and thymine which may be formed following proton or hydrogen exchange between the bases.

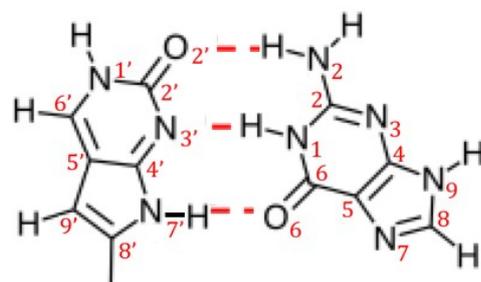

SCHEME 1: Chemical structures of the 2-aminopurine-thymine base pair. The structure on the left, 2AP–T TpI, is analogous to that of the adenine-thymine base pair commonly found in DNA, the structure on the right, 2AP–T TpII, is an alternative hydrogen bonding scheme involving different tautomers of both 2-aminopurine and thymine that may be formed by exchange of protons within the base pair.

The free base 2-aminopurine (2AP) itself has two major tautomers, 9H–2AP and 7H–2AP which exist in water with a 60% : 40% ratio, respectively,<sup>10</sup> however incorporation of 2AP into DNA fixes it in the 9H- tautomeric form. The electronic properties of 2AP are an excitation maximum of 305 nm that is red-shifted compared to adenine,<sup>11</sup> which has an excitation maximum at a wavelength of 260.5 nm.<sup>12</sup> The excited-state lifetimes ( $\tau$ ) of 2-aminopurine and 2-aminopurine riboside in an aqueous

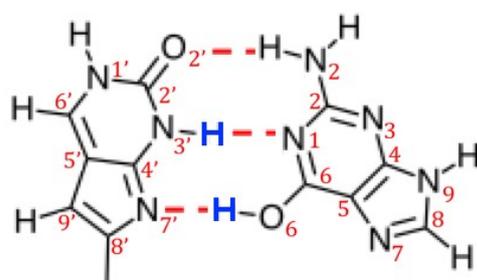

environment (pH = 7) are 11.8 ns and 10.4 ns, respectively, with a fluorescence quantum yield ( $\phi_f$ ) of 0.66 and 0.65, respectively.<sup>13</sup> These values are significantly higher than for the natural DNA bases. However, when 2-aminopurine is incorporated into a single strand of DNA or RNA its fluorescence is quenched, and the fluorescence of 2AP is quenched further still upon formation of a DNA duplex or a DNA:RNA hybrid.<sup>3</sup> It is the sensitivity of 2-aminopurine to base sequence, temperature and helix conformation that enables its use to experimentalists as a fluorescent marker.<sup>14, 15</sup> The low energy absorption maximum of 2AP allows selective and direct excitation when it is incorporated within a synthetic DNA sequence. 2-Aminopurine has been used in numerous and diverse investigations including, as examples: as a marker for microRNA,<sup>16</sup> promoter structure,<sup>17</sup> a sodium ion aptamer,<sup>18</sup> DNA solvation,<sup>19</sup> structural dynamics within DNA<sup>20-22</sup> and protein induced conformational changes.<sup>8,23,24</sup>

Pyrrolocytosine is an analogue of the natural nucleobase cytosine and can form a pseudo Watson-Crick base pair with guanine, as shown in scheme 2.<sup>25</sup> Pyrrolocytosine (PC) has an excitation maximum at a wavelength of 345 nm<sup>25</sup> that is red-shifted compared to cytosine which is excited at a wavelength of 267 nm,<sup>12</sup> and hence may be selectively excited in the presence of the natural nucleobases. The usefulness of pyrrolocytosine is that, like 2AP, the fluorescence quantum yield of pyrrolocytosine is sensitive to the local environment of the nucleic acid in the region in which it is inserted. Tinsley and Walter quantified the extent of fluorescence quenching of pyrrolocytosine inserted into the middle of a single strand of RNA consisting of 20 additional bases, which was also combined with a complementary strand of RNA to form a duplex RNA hairpin.<sup>26</sup> It was found that the steady-state fluorescence of pyrrolocytosine was reduced by ~60% in the single strand RNA and by ~75% in the duplex RNA structure. Pyrrolocytosine has also found application in the study of structure and conformational changes in DNA,<sup>27-29</sup> metal-ion-mediated hybridization of oligonucleotides,<sup>30</sup> base flipping of pyrimidines,<sup>31</sup> investigation of DNA lesions,<sup>32</sup> transcription factor binding<sup>33</sup> and in the design of peptide nucleic acids.<sup>34,35</sup> Scheme 2 shows the expected structure of

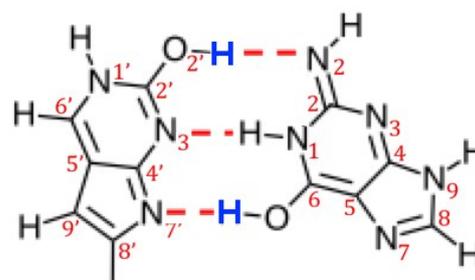

pyrrolocytosine-guanine base pair (PC-G Tpl), based on the hydrogen bonding in the cytosine-guanine base pair. Alternative base pairing can be envisaged involving different tautomeric forms of both pyrrolocytosine and guanine that may be formed by proton transfer within the base pair, these alternative tautomeric pairs are also shown in scheme 2, PC-G TpII and PC-G TpIII.

Pyrrolocytosine                      Guanine

Pyrrolocytosine                      Guanine  
PC-G TplII

Pyrrolocytosine                      Guanine  
PC-G TplIII

SCHEME 2: Chemical structures of the pyrrolocytosine-guanine base pair. The upper structure, PC-G Tpl, is analogous to that of the cytosine-guanine base pair commonly found in DNA, the lower structures, PC-G TplII and PC-G TplIII, are alternative hydrogen bonding schemes involving different tautomers of both pyrrolocytosine and guanine that may be formed by exchange of protons within the base pair.

The reasons why the fluorescence of PC and 2AP are quenched in different environments are still not fully understood but such knowledge would both increase their utility to experimentalists and aid in understanding the properties, and reasons for the ultimate selection of the natural nucleobases during evolution. Although there have been numerous publications on the electronic

properties of the individual, and base stacked, nucleobase analogues pyrrolocytosine and 2-aminopurine,<sup>e.g 15, 36-40</sup> in the present study we have explored the electronic properties of the base pair systems, PG–G and 2AP–T, in particular the different tautomeric forms possible in the base paired systems, and how they may interconvert, considering both the electronic ground state, and electronically excited states. Equilibrium structures for PC–G and 2AP–T base pair tautomers formed as a result of double proton transfer are identified for the ground state ( $S_0$ ) and the first electronic excited state ( $S_1$ ). Potential energy curves for the electronic ground state ( $S_0$ ), the electronic first excited state ( $S_1$ ) and the  $S_0 \rightarrow S_1$  vertical transition are mapped for the transfer of the  $N_3\text{--}(\text{H})N_1$ ,  $N_7(\text{H})\text{--}O_6$  and  $O_2\text{--}(\text{H})N_2$  protons of the pyrrolocytosine-guanine (PC–G) base pair, and for the  $N_1\text{--}(\text{H})N_3$  and  $N_2(\text{H})\text{--}O_2$  protons of the 2-aminopurine-thymine (2AP–T) base pair. Examination of the dipole moment curves for the systems as the protons are transferred are also presented to provide more detail on how the electronic nature of the base pair changes during double proton transfer leading to the formation of the alternative tautomeric pairings.

## MATERIALS AND METHODS

The ground state ( $S_0$ ) geometry of the Tpl pyrrolocytosine-guanine base pair was optimised at MP2/cc-pVDZ level using an input geometry taken from Thompson and Myake,<sup>41</sup> to produce structure Tpl<sub>equi</sub>. Optimized geometries of the other tautomer pairs, TplI<sub>equi</sub> and TplII<sub>equi</sub>, were similarly produced after exchange of the relevant protons. There are three protons shared between pyrrolocytosine and guanine in the PC–G base pair. Double proton transfer can take place between  $N_3\text{--}(\text{H})N_1$  and  $N_7(\text{H})\text{--}O_6$  sites and also between  $O_2\text{--}(\text{H})N_2$  and  $N_7(\text{H})\text{--}O_6$  sites (Scheme 2). Each of the potential energy curves for the  $H_1$ ,  $H_7$  and  $H_2$  proton migrations were constructed by optimising the structure but with the appropriate N–H bond length frozen in increasing 0.1 – 0.2 Å steps up to a maximum bond length of 2.4 Å. All other molecular coordinates were allowed to relax during geometry optimisation and no symmetry constraints were imposed.

The initial geometries for 2-aminopurine-thymine base pair used in this work were taken from Hardman and Thompson<sup>15</sup> and optimised as before. 2-Aminopurine-thymine have two protons that can be exchanged between the bases,  $N_1-(H)N_3$  and  $N_2(H)-O_2$  (Scheme 1). As was the case for the pyrrolocytosine-guanine base pair, the  $H_3$  and  $H_2$  proton transfers of 2-aminopurine-thymine potential energy curves were constructed by freezing the appropriate N–H bond length in increasing 0.1 – 0.2 Å steps up to a maximum of 2.4 Å, and again all other molecular coordinates were allowed to relax during optimisation.

Vertical transition energies were calculated to construct potential energy curves for the  $S_0 \rightarrow S_1$  transition as a function of the relevant proton position. The optimised geometries of the first excited state ( $S_1$ ) were also calculated to define potential energy curves for each of the PC–G and 2AP–T proton transfers. In addition the geometries of the first three excited states ( $S_1$ ,  $S_2$  and  $S_3$ ) of each of the tautomer base pairs considered were also determined. All excited state calculations were performed at the CIS/cc-pVDZ level. The CIS method was selected, rather than time dependent density function methods, TD-DFT, which are of comparable computational cost, because we wished to avoid problems associated with poorly represented charge transfer states between the nucleobases in the base pairs, the energies of which are underestimated by conventional TD-DFT methods, and may be either over or under estimated with long range corrected TD-DFT methods.<sup>15,</sup>

42, 43

MP2 optimised ground state geometries were used as input structures for the excited state calculations. No scaling has been applied to the vertical transition energies or oscillator strengths calculated using the CIS method (unless otherwise stated). To compare the transition energies for the  $\pi \rightarrow \pi^*$  transitions to values in the literature readers may wish to apply a factor of 0.72 as recommended by Broo and Holmén<sup>43</sup> for these states. All calculations for this study were carried out using the Gaussian 03 suite of programs and Molekel was used to visualize molecular geometries and molecular orbitals.<sup>44,45</sup>

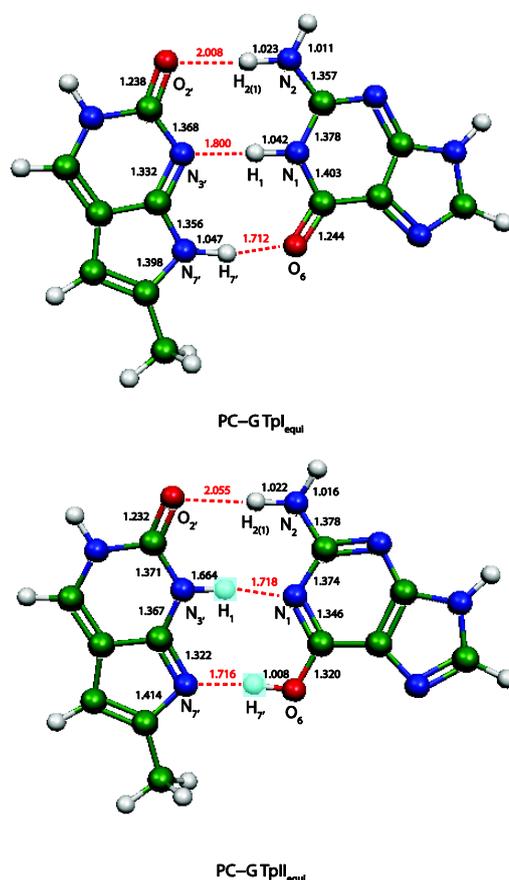

## RESULTS AND DISCUSSION

The results presented in this section for the pyrrolocytosine-guanine and 2-aminopurine-thymine base pairs are from gas phase calculations only. Calculations using the PCM solvation model<sup>46,47</sup> gave qualitatively similar results to the gas phase calculations and are presented in the supplementary information. The results of the geometry optimizations presented below were performed without Counterpoise correction. To estimate the effect of basis set superposition error structures for which optimized geometries were located in the ground electronic state were re-optimised including Counterpoise correction, the results reveal marginally longer, <7%, hydrogen bond lengths in all cases.

### Equilibrium Structures of Ground state Pyrrolocytosine-Guanine Tautomers

Possible base pair tautomers for PC-G are shown in Scheme 2. The tautomer PC-G Tpl is analogous to the Watson-Crick guanine-cytosine base pair, whereas PC-G TplI could potentially be formed by the double proton transfer between  $N_3-(H)N_1$  and  $N_7(H)-O_6'$  and PC-G TplII by the double proton transfer between  $O_2-(H)N_2$  and  $N_7(H)-O_6$ . Optimisation of initial structures to find PC-G Tpl<sub>equi</sub> and PC-G TplI<sub>equi</sub> were successful and showed that PC-G Tpl<sub>equi</sub> is the more stable tautomer pair, with PC-G TplI<sub>equi</sub> lying +7.20 kcal mol<sup>-1</sup> higher in energy. Attempts to find an equilibrium structure of PC-G TplII were not successful, as the system moved back to PC-G Tpl<sub>equi</sub> each time. It will be shown later that this is not unexpected as any minimum for PC-G TplII<sub>equi</sub> is at higher energy than PC-G Tpl<sub>equi</sub> and the minimum would be very shallow. The structures of PC-G Tpl<sub>equi</sub> and PC-G TplI<sub>equi</sub> are shown in Figure 1. In PC-G Tpl<sub>equi</sub> the ring systems were found to be C<sub>s</sub>-

symmetric. This is in contrast to the C-G base pair which, when optimised at the same level, gives a structure where the amino group of guanine show significant pyramidization ( $H_{2'}-N_2-C_2-H_1$  dihedral is  $25^\circ$ ) although the hydrogen bond lengths are all similar (within  $0.02 \text{ \AA}$  of the PC-G Tpl<sub>equi</sub> structure ) and the interaction energy is only slightly smaller (by  $2 \text{ kcal mol}^{-1}$ ). In PC-G Tpl<sub>equi</sub> a slightly propeller twisted structure is found, which is caused by pyramidization of the amino group of guanine, with a  $C_2-C_4'-C_6-C_2$  dihedral angle between the two bases of  $-5.7^\circ$ . The three hydrogen bonds between PC and G are all approximately linear (within  $10^\circ$  of  $180^\circ$ ).

**Figure 1** The ground state ( $S_0$ ) equilibrium geometries of PC-G Tpl<sub>equi</sub> and PC-G Tpl<sub>equi</sub> computed at MP2/cc-pVDZ level. The hydrogen bonds between PC and G, indicated by a dashed red line, are all approximately linear. The lowest energy structure is PC-G Tpl<sub>equi</sub>, with PC-G Tpl<sub>equi</sub> being  $0.31 \text{ eV}$ ,

7.1 kcal mol<sup>-1</sup>, higher in energy. Bond distances are in Angstroms. No such structure is shown for PC-G TpIII as an optimised geometry in the ground state was not located for this tautomer pair.

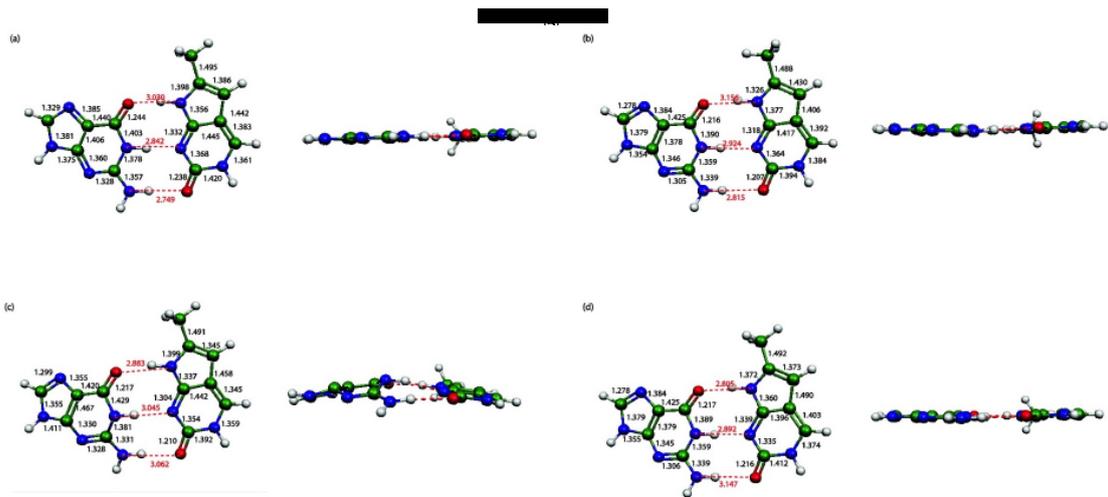

## Vertical Excitation Energies and Equilibrium Structures of Excited State Pyrrolocytosine-Guanine Tautomers

The vertical transition energies from PC-G Tpl<sub>equi</sub> to the first three excited states are shown in Table 1, along with the oscillator strength, *f*, for the transition and the assignment of the state based on the orbitals involved. The geometries of the three excited states, S<sub>1</sub>, S<sub>2</sub> and S<sub>3</sub>, were optimised successfully and are shown in Figure 2. The vertical transition energies to the ground states from the excited states in their optimised geometries are also shown in Table 1.

Transition S <sub>0</sub> to S <sub>x</sub>	Assignment	From optimised S <sub>0</sub> geometry		From optimised S <sub>x</sub> geometry	
		ΔE/eV	<i>f</i>	ΔE/eV	<i>f</i>
X=1	<sup>1</sup> π <sub>PC</sub> <sup>1</sup> π* <sub>PC</sub>	4.77	0.30	4.07	0.27
X=2	<sup>1</sup> π <sub>G</sub> <sup>1</sup> π* <sub>G</sub>	6.16	0.14	4.43	0.17
X=3	<sup>1</sup> π <sub>PC</sub> <sup>1</sup> π* <sub>PC</sub>	6.40	0.02	6.15	0.07

**Table 1** S<sub>0</sub> → S<sub>x</sub> Vertical excitation energies, oscillator strengths and assignments of the three lowest singlet vertical transitions of PC-G Tpl<sub>equi</sub> for geometries optimised in both the S<sub>0</sub> and S<sub>x</sub> states. Calculations performed at CIS/cc-pVDZ level.

A comparison of the optimised geometry of the S<sub>1</sub> state of PC-G Tpl<sub>equi</sub> with the optimised geometry of the ground state (S<sub>0</sub>) shows an increase of up to 0.126 Å in hydrogen bond lengths in the excited state and a slight pyramidization of the amino group of guanine (N<sub>1</sub>C<sub>2</sub>N<sub>2</sub>H<sub>2(1)</sub> dihedral angle = 7.3°, Figure 2). Changes to intramolecular bond lengths mostly affect pyrrolocytosine (Figure 2), supporting the assignment to the local excitation of the pyrrolocytosine monomer.

**Figure 2** Optimised geometries, in plane and profile views, of the ground state ( $S_0$ ) PC–G Tpl<sub>equi</sub> base pair (computed at MP2/cc-pVDZ level) (a), with first ( $S_1$ ), second ( $S_2$ ) and third ( $S_3$ ) optimised electronic excited state geometries (b), (c), (d), respectively (computed at CIS/cc-pVDZ). The hydrogen bonds between PC and G, indicated by a dashed red line, are all approximately linear. Bond distances are in Angstroms.

The optimised PC–G Tpl<sub>equi</sub> geometry of the second ( $S_2$ ) excited state has a buckled structure (Figure 2). The source of this distortion lies not in the pyramidization of the guanine amino group, but is due to an out-of-plane deformation of the ring structure of guanine caused by a twisting and shortening, from 1.360 Å in the  $S_0$  state to 1.330 Å in the  $S_2$  state, of the N<sub>3</sub>C<sub>4</sub> bond.

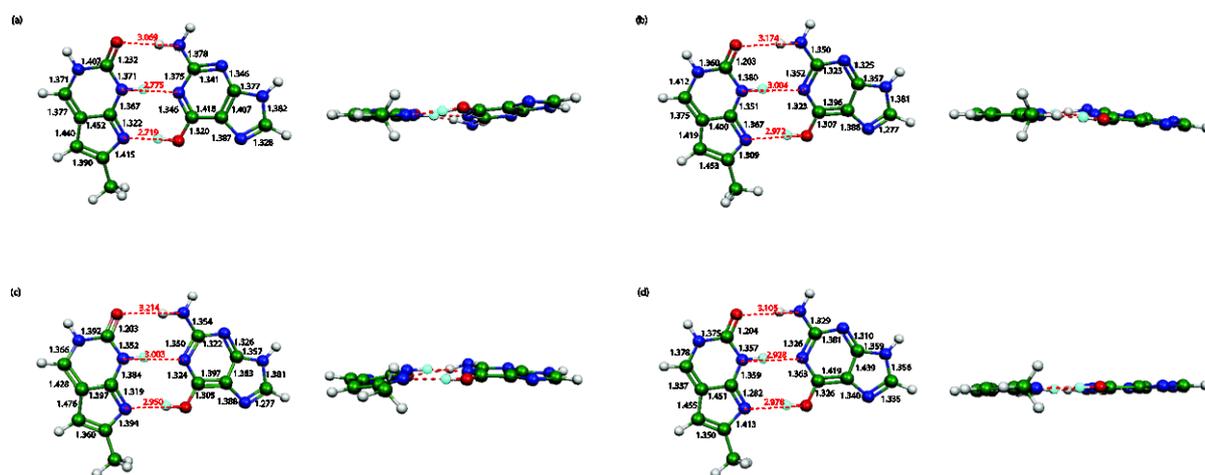

The optimised geometry of the third excited state ( $S_3$ ) of the PC–G Tpl<sub>equi</sub> base pair (Figure 2) is essentially  $C_s$ -symmetric with a slight pyramidization of the amino group of guanine (C<sub>2</sub>:C<sub>4</sub>:C<sub>6</sub>C<sub>2</sub> dihedral angle of  $-1.3^\circ$ ). Hydrogen bond lengths have changed and there have been greater changes to intramolecular bond lengths affecting pyrrolocytosine, supporting the transition of  ${}^1\pi_{PC} \rightarrow {}^1\pi_{PC}^*$ .

For PC–G TpII, a comparison of the structure in the ground state ( $S_0$ ) with the structure in the optimised first, second and third excited states ( $S_1$ ,  $S_2$ , and  $S_3$ ) all show an increase in hydrogen bond lengths (Figure 3). Changes to intramolecular bond lengths for the  $S_1$  optimised PC–G TpII<sub>equi</sub> structure mostly affect pyrrolocytosine, which is consistent with the local excitation of the pyrrolocytosine monomer (Table 2), again there is slight pyramidization of the amino group of guanine ( $N_1C_2N_2H_{2(1)}$  dihedral angle =  $-16.4^\circ$ ).

Transition $S_0$ to $S_x$	Assignment	From optimised $S_0$ geometry		From optimised $S_x$ geometry	
		$\Delta E/eV$	$f$	$\Delta E/eV$	$f$
X=1	$^1\pi_{PC}^1\pi_{PC}^*$	4.50	0.19	3.85	0.11
X=2	$^1\pi_{PC}^1\pi_{PC}^*$	5.94	0.34	5.70	0.36
X=3	$^1\pi_G^1\pi_G^*$	6.13	0.28	5.89	0.44

**Table 2**  $S_0 \rightarrow S_x$  Vertical excitation energies, oscillator strengths and assignments of the three lowest singlet vertical transitions of PC–G TpII<sub>equi</sub> for geometries optimised in both the  $S_0$  and  $S_x$  states.

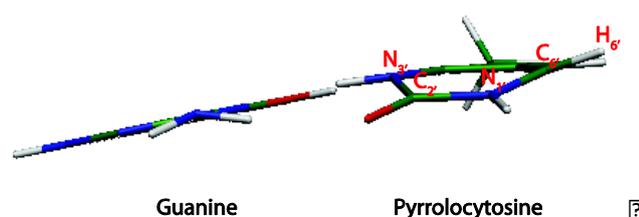

Calculations performed at CIS/cc-pVDZ level.

**Figure 3** Optimised geometries, in plane and profile views, of the ground state PC–G TpII<sub>equi</sub> base pair (computed at MP2/cc-pVDZ level) (a), with first ( $S_1$ ), second ( $S_2$ ) and third ( $S_3$ ) optimized electronic

excited state geometries (b), (c), (d), respectively (computed at CIS/cc-pVDZ). A dashed red line indicates the hydrogen bonds between PC and G. Bond distances are in Angstroms.

The  $S_2$  optimised structure of PC–G TplI<sub>equi</sub> is interesting, as it is an example of significant distortion of pyrrolocytosine due to twisting of the  $N_1'C_6'$  bond and the  $H_1'N_1'C_6'H_6'$  dihedral angle is  $-15.9^\circ$ , as shown in Figure 4. Perun *et al.* have observed that an out-of-plane deformation of a ring structure, such as is observed with PC–G TplI<sub>equi</sub> in the second ( $S_2$ ) excited state, is associated with nearby conical intersections and thus potentially fast, non-radiative routes back to the ground state.<sup>48,49</sup> The optimised geometry of the third excited state ( $S_3$ ) of PC–G TplI<sub>equi</sub> is  $C_s$ -symmetric (Figure 3), with the greatest changes to the intramolecular bond lengths being for guanine, consistent with local excitation of that base (Table 2).

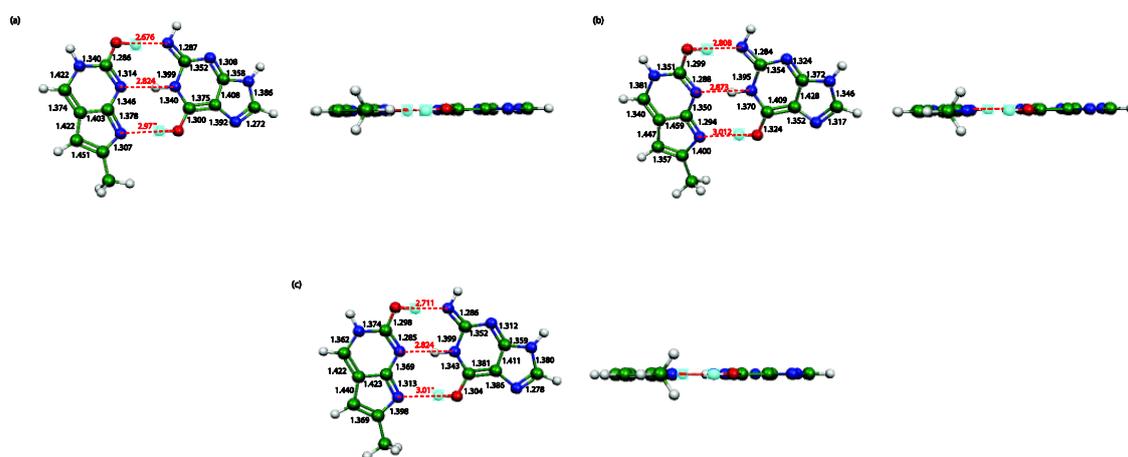

**Figure 4** Optimised geometry of the  $S_2$  excited state of the PC–G TplI<sub>equi</sub> structure, showing the distortion caused by twisting of the  $N_1'C_6'$  bond. The  $H_1'N_1'C_6'H_6'$  dihedral angle is  $-15.9^\circ$ . Such twisting may be associated with nearby conical intersections and thus provide a fast, non-radiative, route back to the ground electronic state.

The PC-G TpIII structure, which could not be successfully optimised in the ground electronic state, was successfully optimised in the three lowest lying electronically excited states: Table 3 shows the energies of the optimised geometries whilst the structures, which are all  $C_5$ -symmetric, are shown in Figure 5.

From optimised $S_x$ geometry			
Transition	Assignment	$\Delta E/eV$	$f$
$S_0$ to $S_x$			
X=1	${}^1\pi_{PC}{}^1\pi^*_{PC}$	4.72	0.10
X=2	${}^1\pi_G{}^1\pi^*_G$	6.18	0.24
X=3	${}^1\pi_{PC}{}^1\pi^*_{PC}$	6.61	0.33

**Table 3** Vertical transition energies, oscillator strengths and assignment of the three lowest transitions between the ground electronic state and the geometry optimised excited states of the PC-G TpIII<sub>equi</sub> base pair. Calculations performed at CIS/cc-pVDZ level. Note excitation energies from the optimised ground state are not given as no optimised ground state structure was located.

?

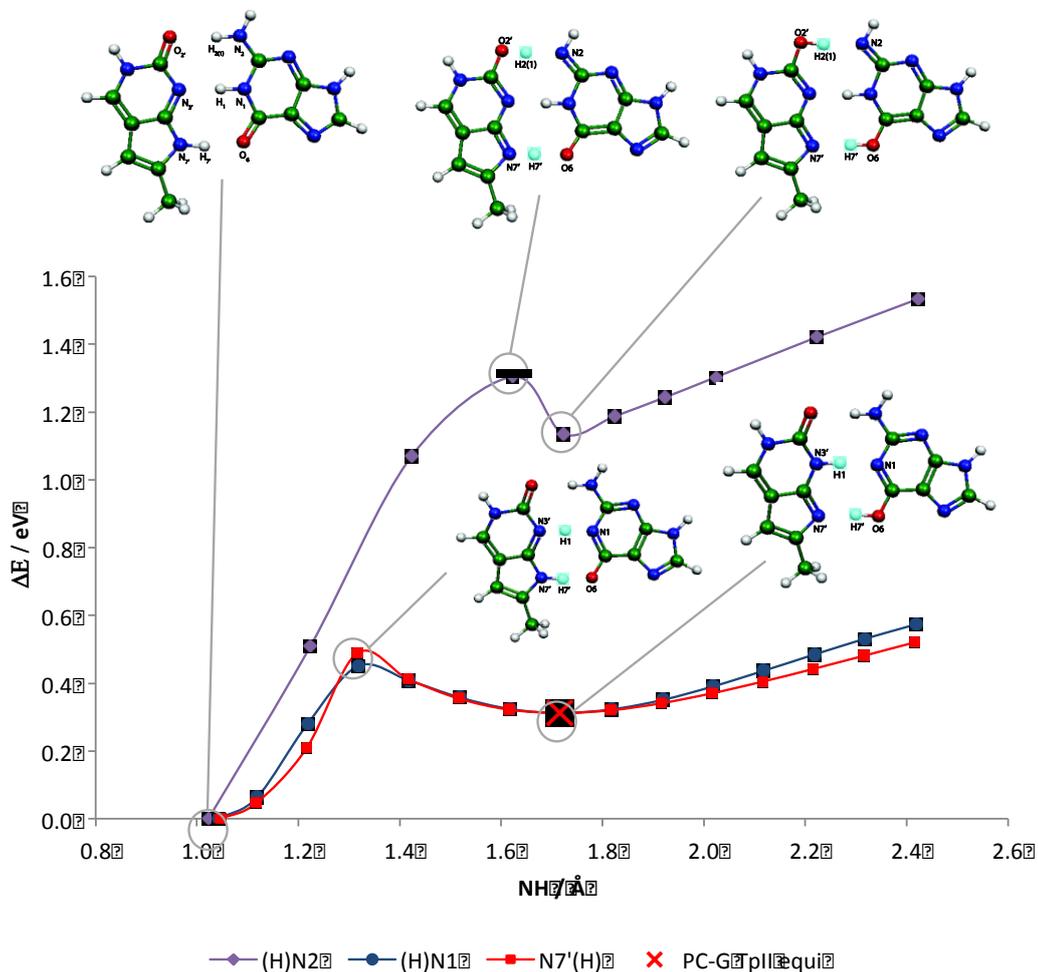

**Figure 5** Optimised geometries, in plane and profile views, of the first ( $S_1$ ), second ( $S_2$ ) and third ( $S_3$ ) electronic excited state of PC-G TplIII<sub>equi</sub>, (a), (b) and (c), respectively (computed at CIS/cc-pVDZ). A dashed red line indicates the hydrogen bonds between PC and G. Bond distances are in Angstroms. No optimised structure for PC-G TplIII in its ground electronic state was located.

### Pyrrolocytosine-Guanine Proton Transfer Potential Energy Curves in the electronic ground state

Potential energy curves for the transfer of a proton between the bases were constructed by performing a geometry optimisation whilst freezing the relevant N–H bond. As the N–H bond was frozen at longer and longer distances a proton (or potentially a hydrogen) from the other base migrated in the opposite direction, hence tautomer base pairs were formed. The general form of the potential energy curves consist of increasing energy as the frozen bond length is increased, leading to a local energy maximum (LEnergy<sub>max</sub>), followed by a local energy minimum (LEnergy<sub>min</sub>) when the two bases have essentially swapped protons (or hydrogens) and an alternative tautomer base pair has formed. From examination of Figure 6, which shows the potential energy curves for each of the three ground state proton transfers from PC-G Tpl<sub>equi</sub>, it can be seen that the (H)N<sub>1</sub> and N<sub>7</sub>(H) potential energy curves have very similar profiles, which is to be expected as the result in both

cases is that the same two protons ( $(\text{H})\text{N}_1$  and  $\text{N}_7(\text{H})$ ) have been exchanged between pyrrolocytosine and guanine. There is a slight difference ( $\Delta E = \pm 0.04$  eV or  $\pm 0.9$  kcal mol<sup>-1</sup>) in the barrier heights ( $\text{LEnergy}_{\text{max}}$ ) between these two potential energy curves. The  $\text{LEnergy}_{\text{min}}$  structure formed in both cases could be optimised without any imposed geometry constraint to form PC-G  $\text{Tpl}_{\text{equi}}$ .

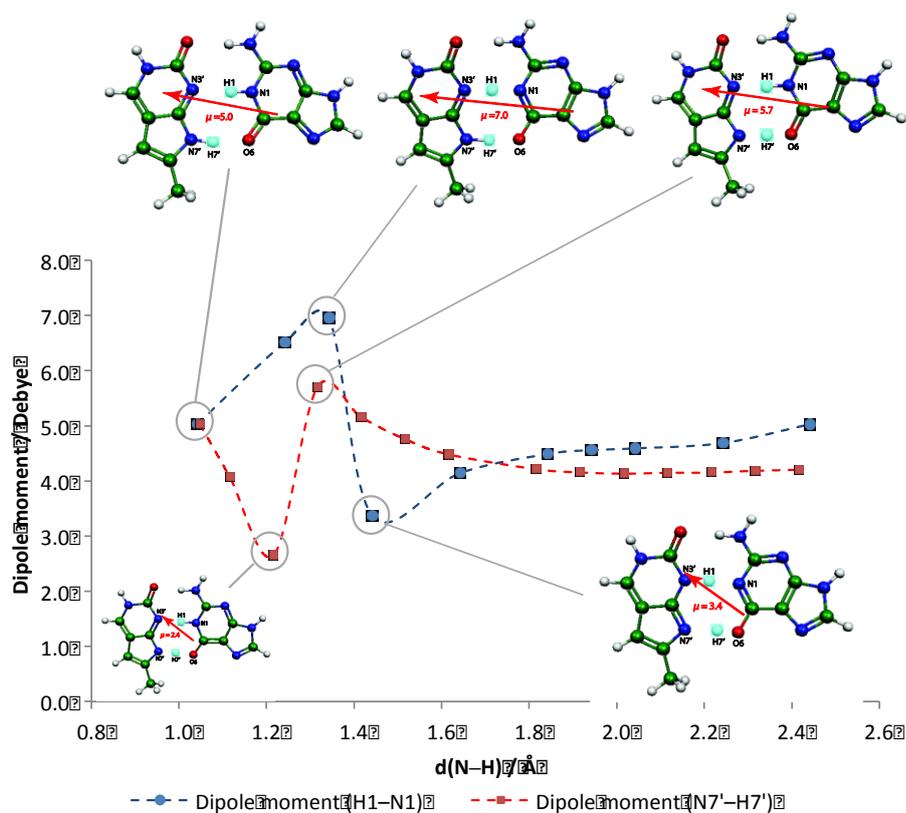

The dipole moment of PC-G  $\text{Tpl}_{\text{equi}}$  ( $\mu = 3.4$  D) is a little higher than that of PC-G  $\text{Tpl}_{\text{equi}}$  ( $\mu = 2.4$  D). Examination of the changes in dipole moments for the formation of PC-G  $\text{Tpl}_{\text{equi}}$  from PC-G  $\text{Tpl}_{\text{equi}}$  (shown in Figure 7) reveals that the changes are quite different depending upon which proton is initially migrated. Initial migration of the  $\text{H}_1$  proton of guanine initially increases the dipole moment between guanine and pyrrolocytosine. At the  $\text{LDipole}_{\text{max}}$  structure (blue curve in Figure 7) the dipole moment is 7.0 D. The dipole moment is partially reduced by migration of a second proton ( $\text{H}_7$ ) from pyrrolocytosine to guanine. Initial migration of  $\text{H}_7$  from pyrrolocytosine to guanine however initially decreases the dipole moment as positive charge is being transferred from pyrrolocytosine to guanine, however the migration of the second proton ( $\text{H}_1$ ) from guanine to pyrrolocytosine increases the dipole moment again.

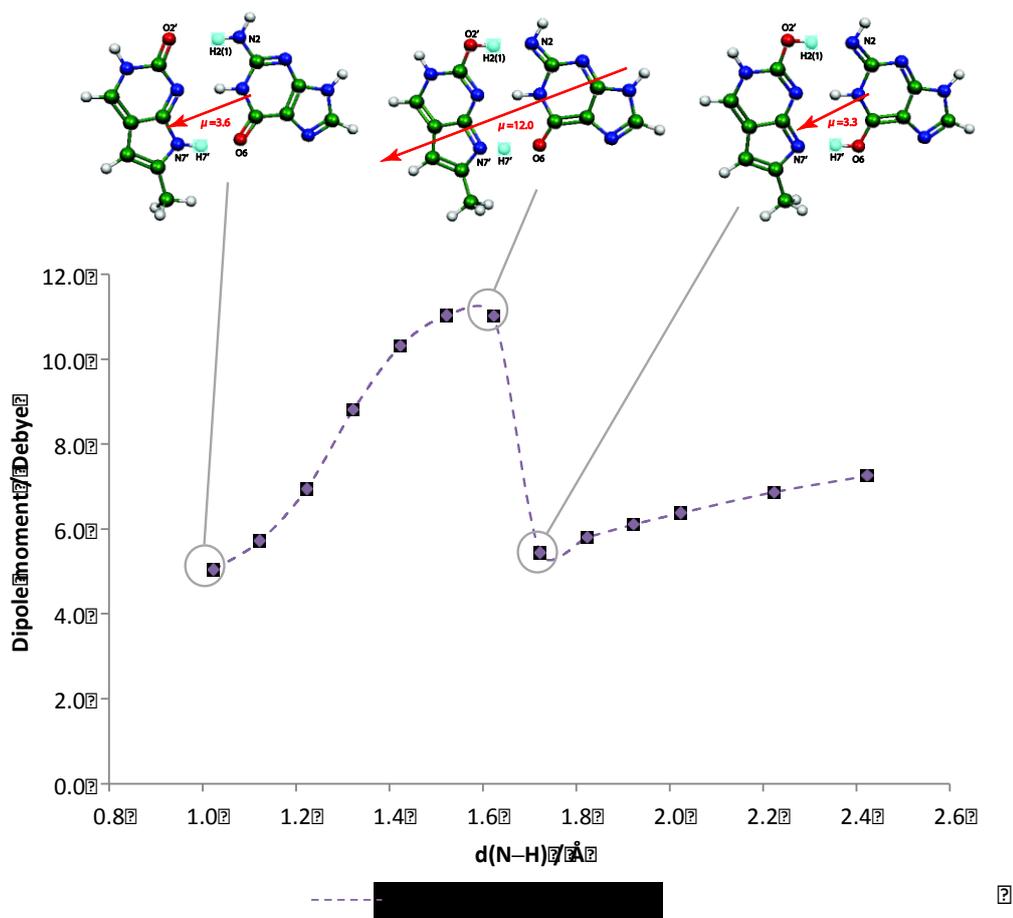

**Figure 6** Change in energy of the optimised ground state ( $S_0$ ) geometry as a function of H–N distance for the proton transfer processes from the PC–G Tpl<sub>equi</sub> structure. The top row of structures and violet line refer to moving the  $\text{O}_2-(\text{H})\text{N}_2$  proton, showing the initial PC–G Tpl<sub>equi</sub> structure, a local energy maximum (LEnergy<sub>max</sub>) structure at  $(\text{H})\text{N}_2$  at  $1.623 \text{ \AA}$  and a local energy minimum (LEnergy<sub>min</sub>) structure at  $(\text{H})\text{N}_2$   $1.723 \text{ \AA}$  and a  $\text{O}_2(\text{H})$  distance of  $1.033 \text{ \AA}$ . Unrestricted geometry optimisation of the LEnergy<sub>min</sub>  $(\text{H})\text{N}_2-\text{N}_7(\text{H})$  double proton transfer structure was not successful in that a structure for PC–G TplI<sub>equi</sub> was not located, rather the system reverted to PC–G Tpl<sub>equi</sub>. The lower pair of structures refer to moving the  $\text{N}_3'-(\text{H})\text{N}_1$  (blue line) and  $\text{N}_7'(\text{H})-\text{O}_6$  (red line) protons: the left figure showing a local energy maximum (LEnergy<sub>max</sub>) at  $\text{N}_7'(\text{H}) = 1.316 \text{ \AA}$  and the right figure showing the

structure of PC-G Tpl<sub>equi</sub> (✗ on potential energy curve) produced by unrestricted geometry optimisation.

As the (H)N<sub>2</sub> proton migrates from the amino group of guanine to pyrrolocytosine, a local energy maximum (LEnergy<sub>max</sub>) is reached at a (H)N<sub>2</sub> bond length of 1.623 Å (Figure 6) and forms a barrier  $\Delta E = 1.30$  eV (30.0 kcal mol<sup>-1</sup>) above the PC-G Tpl<sub>equi</sub> ground state energy. The migration of a second proton H<sub>7</sub>, from pyrrolocytosine to guanine, leads to the formation of a local energy minimum (LEnergy<sub>min</sub>) structure at (H)N<sub>2</sub> = 1.723 Å, but the reduction in energy is only slight and this LEnergy<sub>min</sub> structure reverted to PC-G Tpl<sub>equi</sub> upon attempts to optimise it. During transfer of the (H)N<sub>2</sub> proton from guanine to pyrrolocytosine the magnitude of the maximum dipole moment (LDipole<sub>max</sub>), shown in Figure 8, is higher by at least 7.0 D than was found for the (H)N<sub>1</sub> and N<sub>7</sub>(H) proton transfers, indicating increased charge separation as the (H)N<sub>2</sub> proton is transferred from one moiety to the other.

**Figure 7** Dipole moment as a function of N–H distance for the (H)N<sub>1</sub> and N<sub>7</sub>(H) proton transfers from the ground state (S<sub>0</sub>) optimised PC–G Tpl<sub>equi</sub> structure. Showing (top row of figures left to right) PC–G Tpl<sub>equi</sub> structure, LDipole<sub>max</sub> for (H)N<sub>1</sub> proton transfer and LDipole<sub>max</sub> for N<sub>7</sub>(H) proton transfer. Left inset figure is LDipole<sub>min</sub> for N<sub>7</sub>(H) proton transfer and right inset figure is LDipole<sub>min</sub> for N<sub>1</sub>(H) proton transfer.

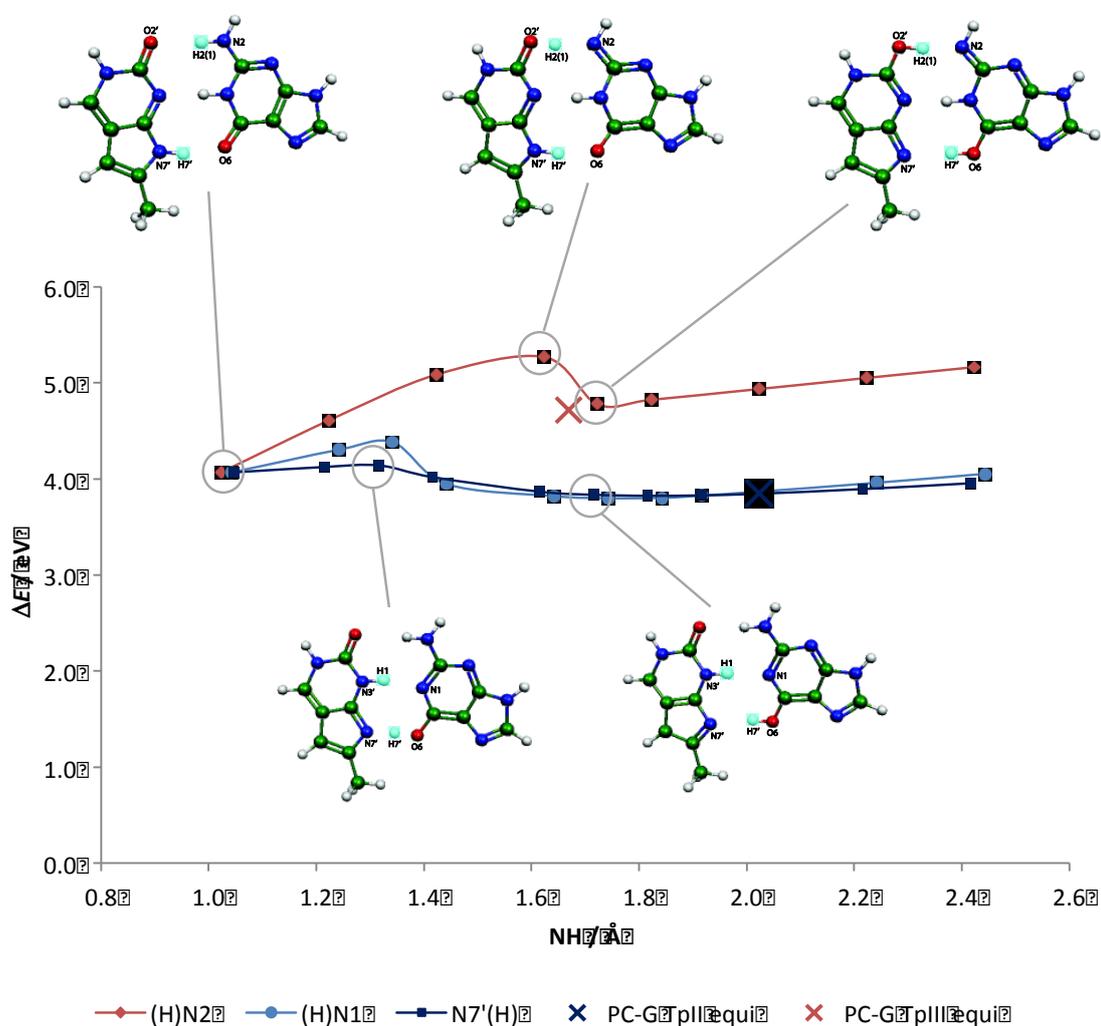

**Figure 8** Change in dipole moment of the optimised ground state ( $S_0$ ) geometry as a function of  $H_2$  to  $N_2$  distance for the proton transfer process  $O_2-(H)N_2$  from PC-G  $Tpl_{equi}$ . Showing the  $Tpl_{equi}$  structure of PC-G, a local maximum in the dipole moment of  $(H)N_2$  at 1.623 Å and a local minimum in the dipole moment at  $(H)N_2$  1.723 Å and a  $O_2(H)$  distance of 1.033 Å.

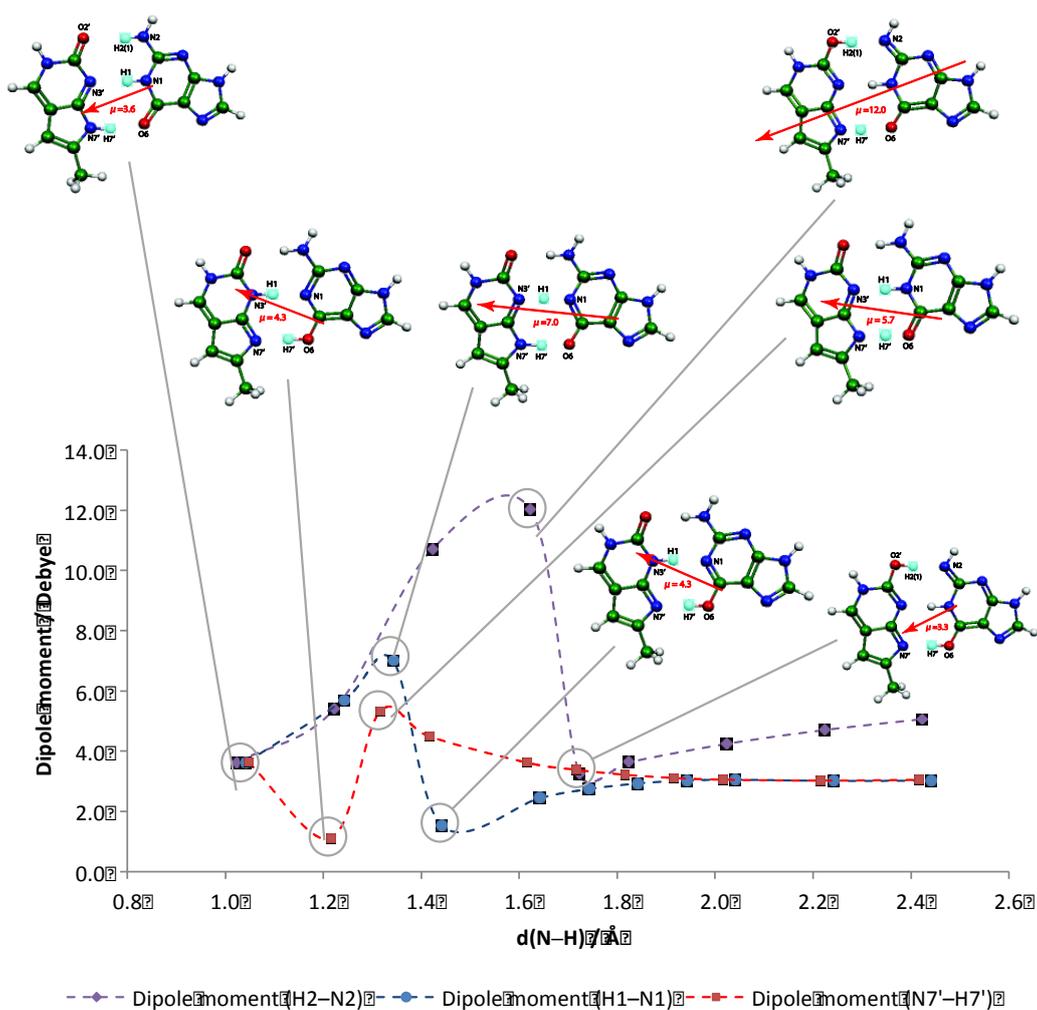

### Pyrrolocytosine-Guanine Proton Transfer Potential Energy Curves in electronically excited states

Transfer of protons to form alternative tautomer pairs in the first electronically excited state was explored in a similar manner to the ground state, by performing a, in this case excited state,

geometry optimisation whilst freezing the relevant N–H bonds at increasing longer lengths. The potential energy (Figure 9) and dipole moment curves (Figure 10) for the PC–G proton transfers in the first excited state have a very similar profile to those of the ground state ( $S_0$ ) (Figures 6,7 and 8), the key difference being that although in the ground electronic state it was not possible to optimise PC–G  $TpIII_{equi}$ , this was possible in the first excited state ( $S_1$ ).

**Figure 9** Potential energy as a function of N–H distance for the (H)N<sub>2</sub>, (H)N<sub>1</sub>, N<sub>7</sub>(H) proton transfers from the S<sub>1</sub> PC–G Tpl<sub>equi</sub> structure, and the energies of the PC–G Tpl<sub>equi</sub> (✕) & PC–G Tpl<sub>equi</sub> (✕) optimised S<sub>1</sub> geometries. Calculations were performed at the CIS/cc-pVDZ level. In the S<sub>1</sub> state the PC–G Tpl<sub>equi</sub> structure is lower in energy than the PC–G Tpl<sub>equi</sub> structure.

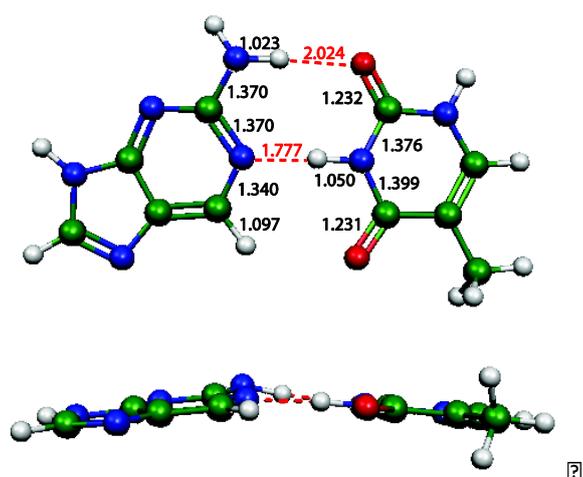

**Figure 10** Dipole moment as a function of N–H distance for the (H)N<sub>2</sub>, (H)N<sub>1</sub> and N<sub>7</sub>(H) proton transfers from the PC–G Tpl<sub>equi</sub> structure in the S<sub>1</sub> optimised geometries. Showing (top row of figures left to right) PC–G Tpl<sub>equi</sub> and LDipole<sub>max</sub> for (H)N<sub>2</sub> proton transfer; (middle row of figures left to right) LDipole<sub>min</sub> for N<sub>7</sub>(H), LDipole<sub>max</sub> for (H)N<sub>1</sub> and LDipole<sub>max</sub> for N<sub>7</sub>(H) proton transfers; (bottom row of figures left to right) LDipole<sub>min</sub> for (H)N<sub>1</sub> and (H)N<sub>2</sub> for LDipole<sub>min</sub> proton transfers.

### Possible conversion pathways between PC–G Tpl , PC–G TplI and PC–G TplII

PC–G Tpl is the more stable structure in the ground electronic state, whilst PC–G TplI is more stable in the first excited state. In the ground state only a very small fraction of PC–G would be expected in PC–G TplI as this structure is over 7 kcal mol<sup>-1</sup> higher in energy than PC–G Tpl. Excitation of PC–G Tpl to S<sub>1</sub> requires 4.77 eV (Table 1), which could lose 0.70 eV as it undergoes vibrational relaxation to the optimised S<sub>1</sub> structure of PC–G Tpl, which is 4.07 eV above the ground state. However, as the energy of optimised geometry of PC–G TplI in the first excited state, 3.85 eV, is lower by 0.22 eV (5 kcal mol<sup>-1</sup>), than the initially formed excited state PC–G Tpl, double proton transfer is possible to yield PC–G TplI in the excited state. Note that 4.77 eV is higher in energy than the barrier at about 1.3 Å shown on Figure 9. Once formed in the excited state PC–G TplI<sub>equi</sub> would provide an alternative route back to the ground electronic state, either via fluorescence back to the ground electronic state of PC–G TplI or via some other route. Once formed, ground state PC–G TplI could convert back to PC–G Tpl by crossing the local energy maximum barrier, 3.205 kcal mol<sup>-1</sup> at 1.318 Å shown on Figure 6. Excitation of PC–G Tpl to the first excited state does not provide sufficient energy to cross the barrier located at about 1.6 Å required to form PC–G TplII in the first excited state by double proton transfer.

### Equilibrium Structure of Ground state 2-Aminopurine-Thymine Tautomers

Two possible tautomer pairs for 2-aminopurine-thymine (2AP-T) are shown in Scheme 1. The MP2 optimised geometry of the 2AP-T Tpl<sub>equi</sub> base pair, equivalent to the lowest energy tautomer pair for the natural base pair A-T, was the only tautomer pair for which a minimum energy structure was found in the ground electronic state. The optimised structure is buckled (Figure 11), owing to pyramidization of the amino group of 2-aminopurine (2AP) with a N<sub>1</sub>C<sub>2</sub>N<sub>2</sub>H<sub>2'(1)</sub> dihedral angle of 22.3°. This pyramidization of the amino group of 2-aminopurine is greater than that seen in the equivalent structure for A-T, where the H<sub>2</sub>-N<sub>6</sub>-C<sub>6</sub>-N<sub>1</sub> dihedral angle is 12.5° when A-T is optimised at the same level. The thymine in the 2AP-T and A-T base pairs has a flat ring structure. The two hydrogen bonds between 2AP and T are approximately linear, as expected (within 5° of 180°). The equivalent two hydrogen bonds lengths and angles in the A-T base pair optimised at the same level are within 0.1 Å and 2° of those in 2AP-T.

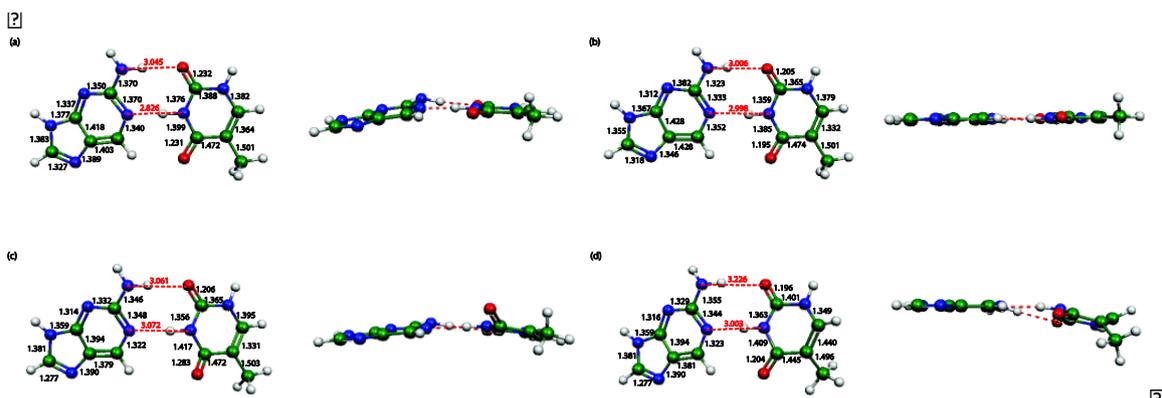

**Figure 11** The ground state ( $S_0$ ) equilibrium geometry of 2AP-T Tpl<sub>equi</sub> at MP2/cc-pVDZ level. Bond lengths are given in Angstroms. No such structure is shown for 2AP-T Tpl<sub>II</sub> as an optimised geometry in the ground state was not located for this tautomer pair.

### Vertical Excitation Energies and Equilibrium Structures of Excited State 2-Aminopurine-Thymine Tautomers

The vertical transition energies from 2AP–T Tpl<sub>equi</sub> to the first three excited states are shown in Table 4, along with the oscillator strength, *f*, for the transition and the assignment of the state based on the orbitals involved. The geometries of the three excited states, S<sub>1</sub>, S<sub>2</sub> and S<sub>3</sub>, were optimised successfully and are shown in Figure 12. The vertical transition energies from the optimized excited states to the ground states are also shown in Table 4. The hydrogen bond lengths of the 2AP–T Tpl<sub>equi</sub> base pair in the ground state (S<sub>0</sub>), first (S<sub>1</sub>), second (S<sub>2</sub>) and third (S<sub>3</sub>) excited states are shown in Figure 12.

Transition	Assignment	From optimised S <sub>0</sub> geometry		From optimised S <sub>x</sub> geometry	
		ΔE/eV	<i>f</i>	ΔE/eV	<i>f</i>
S <sub>0</sub> to S <sub>x</sub>					
X=1	<sup>1</sup> π <sub>2AP</sub> <sup>1</sup> π* <sub>2AP</sub>	5.57	0.38	5.12	0.41
X=2	<sup>1</sup> n <sub>T</sub> <sup>1</sup> π* <sub>T</sub>	6.30	0.00	4.85	0.00
X=3	<sup>1</sup> π <sub>T</sub> <sup>1</sup> π* <sub>T</sub>	6.42	0.30	5.32	0.16

**Table 4** S<sub>0</sub> → S<sub>x</sub> Vertical excitation energies, oscillator strengths and assignments of the three lowest singlet vertical transitions of the optimised geometries of the 2AP–T Tpl<sub>equi</sub> for geometries optimised in both the S<sub>0</sub> and S<sub>x</sub> states. Calculations performed at CIS/cc-pVDZ level.

**Figure 12** Optimised geometries, in plane and profile views, of the ground state ( $S_0$ ) 2AP–T  $Tpl_{equi}$  base pair (computed at MP2/cc-pVDZ level), (a), and the first ( $S_1$ ), second ( $S_2$ ) and third ( $S_3$ ) electronic excited state geometries (b), (c), (d), respectively (computed at CIS/cc-pVDZ). A dashed red line indicates the hydrogen bonds between 2AP and T.

Bond distances are in Angstroms.

The third transition ( $S_3$ ) of 2AP–T  $Tpl_{equi}$  is interesting in terms of changes to the geometry of the base pair, shown by twisting of the  $C_5C_6$  double bond of thymine which has a  $H_6C_6C_5C_7$  dihedral angle of  $-61.2^\circ$ . This distortion may indicate the presence of a nearby conical intersection present in thymine, as described by Perun *et al.*,<sup>49</sup> which features out-of-plane distorted geometries of the six-membered heteroaromatic ring. Whereby, the  $H_6$  atom and methyl group are twisted out of the plane of the ring (Figure 12) and the  $C_5C_6$  bond increases in length by  $0.076 \text{ \AA}$ . These geometrical changes in thymine are consistent with  ${}^1LE(\pi_T\pi_T^*)$  excitation.

The 2AP–T  $Tpl_{II}$  structure can be formed by exchanging a proton from the  $(H)N_3$  of thymine to 2-aminopurine and the  $N_2(H)$  of 2-aminopurine to thymine. Although an optimised structure for 2AP–T  $Tpl_{II}$  could not be found in the ground electronic state, this tautomeric pair could be successfully optimised in the first electronically excited state, although it was higher in energy than the first

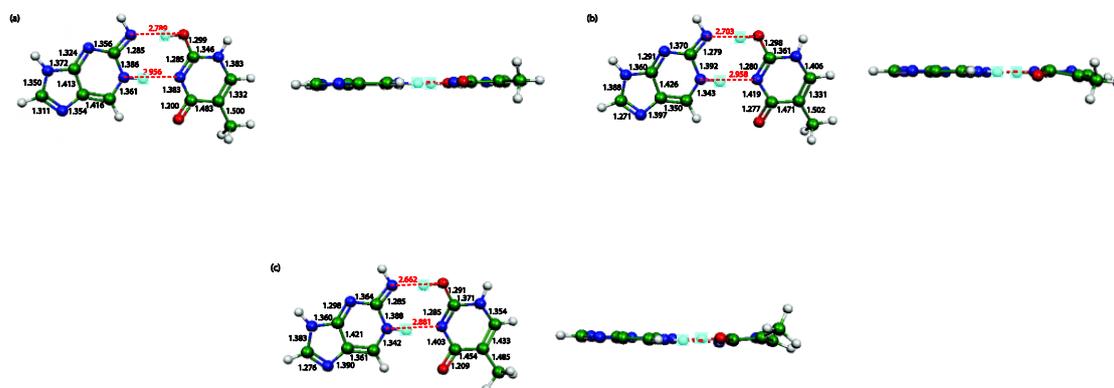

excited state of the 2AP-T  $\text{TpI}_{\text{equi}}$  structure. The  $S_1$  structure of 2AP-T  $\text{TpII}_{\text{equi}}$  has a  $\text{N}_2'(\text{H})$  bond length of 1.812 Å with a  $\Delta E = 0.40$  eV (9.2 kcal mol<sup>-1</sup>) above the  $S_1$  optimised 2AP-T  $\text{TpI}_{\text{equi}}$  structure. Table 5 shows the vertical transition energies from the optimised geometries of the three lowest lying excited states of 2AP-T  $\text{TpII}_{\text{equi}}$ . Vertical transition energies from the optimised ground state ( $S_0$ ) are not shown since 2AP-T  $\text{TpII}_{\text{equi}}$  could not be optimised in its ground state ( $S_0$ ) geometry.

From optimised $S_x$ geometry			
Transition	Assignment	$\Delta E/eV$	$f$
$S_0$ to $S_x$			
X=1	${}^1\pi_{2AP}{}^1\pi_{2AP}^*$	5.53	0.24
X=2	${}^1\pi_T{}^1\pi_T^*$	6.62	0.23
X=3	${}^1n_T{}^1\pi_T^*$	6.66	0.00

**Table 5** Vertical transition energies, oscillator strengths,  $f$ , and assignment of the three lowest transitions of the optimised geometries of the 2AP–T TplI<sub>equi</sub> 2-aminopurine-thymine base pair. Calculations performed at CIS/cc-pVDZ level. Note excitation energies from the optimised ground state are not given as no optimised ground state structure was located.

The geometries of the optimised  $S_1$ ,  $S_2$  and  $S_3$  structures of 2AP–T TplI<sub>equi</sub> are shown in Figure 13. The geometry of 2AP–T TplI<sub>equi</sub> in the first excited state ( $S_1$ ) is flat with a  $C_6C_2C_2C_4$  dihedral angle of  $0.0^\circ$ , whereas the optimised geometry of the second excited state ( $S_2$ ) has a puckered structure, due to twisting of the  $N_1C_6$  bond of thymine, with a  $H_1N_1C_6H_6$  dihedral angle of  $17.4^\circ$ . The  $S_3$  optimised structure of 2AP–T TplI<sub>equi</sub> is also distorted, here by a twisting of the  $C_5C_6$  bond of thymine, with a  $C_7C_5C_6H_6$  dihedral angle of  $37.5^\circ$ .

**Figure 13** Optimised geometries, in plane and profile views, of the 2-aminopurine-thymine base pair with first ( $S_1$ ), second ( $S_2$ ) and third ( $S_3$ ) electronic excited state geometries of 2AP–T TplI<sub>equi</sub> (a), (b) and (c), respectively (computed at CIS/cc-pVDZ). A dashed red line indicates the hydrogen bonds between 2AP and T. Bond distances are in Angstroms.

### 2-Aminopurine-Thymine Proton transfer Potential Energy Curves in the electronic ground state

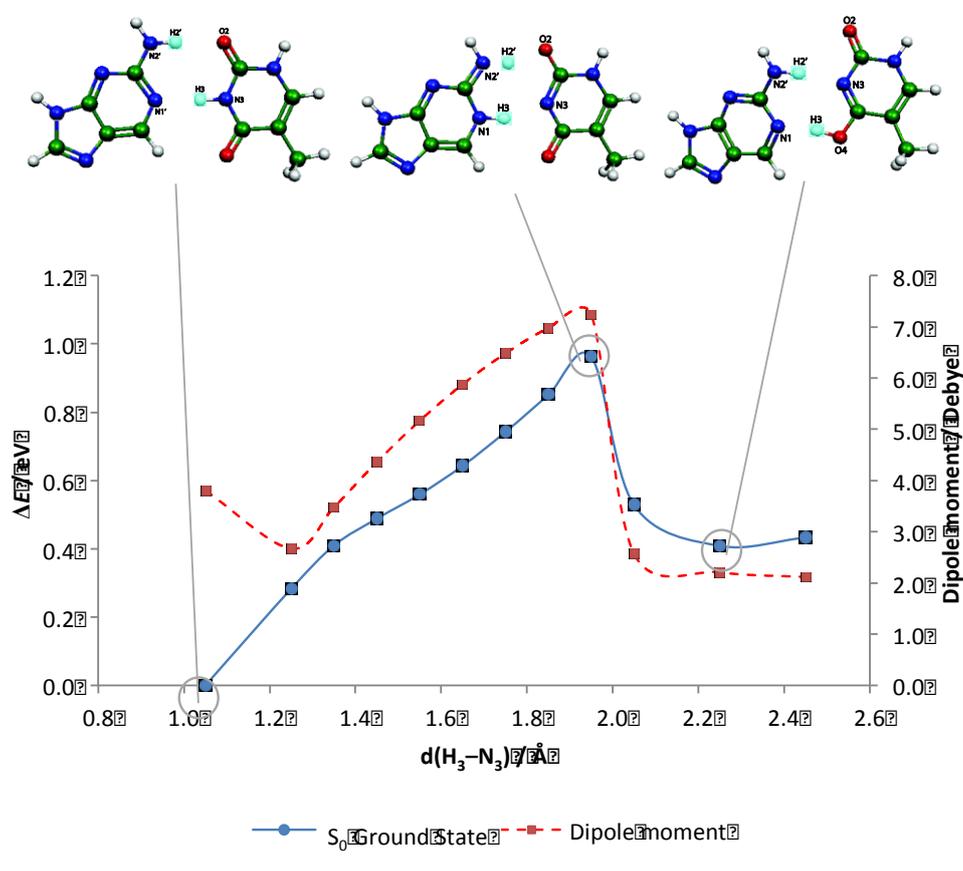

Examination of the potential energy curve (Figure 14) for the migration of the  $N_2(H)$  proton from 2-aminopurine to thymine, in the ground electronic state, shows that there are no clearly defined  $LEnergy_{max}$  or  $LEnergy_{min}$  structures observed as was previously seen for the potential energy curves of proton transfer in the pyrrolocytosine-guanine base pair, and, as has been noted previously, no optimised structure was found for 2AP–T TplI. Any attempt to optimise the structure at the  $LDipole_{min}$  without imposed geometry constraints produces the 2AP–T Tpl<sub>equi</sub> structure.

**Figure 14** Change in energy of the optimised ground state ( $S_0$ ) geometry as a function of  $N_2'$  to  $H_2'$  distance of the gas phase 2AP-T Tpl<sub>equi</sub> base pair for the proton transfer process  $N_2'(H)-O_2$ . Showing the 2AP-T Tpl<sub>equi</sub> structure, a local dipole maximum (LDipole<sub>max</sub>) of  $N_2'(H)$  at 1.343 Å and a local dipole minimum (LDipole<sub>min</sub>) at  $N_2'(H) = 1.443$  Å and a (H) $O_2$  distance of 1.121 Å. No LEnergy<sub>min</sub> structure for 2AP-T TplII was located and unrestricted geometry optimisation of initial geometries for 2AP-T TplII, performed at MP2/cc-pVDZ level, did not locate a minimum energy structure for this tautomer pair.

Migrating the proton (or hydrogen) from (H) $N_3$  first leads to a slightly different situation (Figure 15). A local energy maximum structure was located at a relatively large (H) $N_3$  bond distance, (H) $N_3 = 1.950$  Å, with an energy barrier of  $\Delta E = 0.96$  eV (22.1 kcal mol<sup>-1</sup>) above the 2AP-T Tpl<sub>equi</sub> structure.

However, as the migration of the (H)N<sub>3</sub> proton proceeds the alignment of hydrogen bond donors and acceptors adjusts and the previously migrated (H)N<sub>3</sub> proton is now attached to the O<sub>4</sub> atom of thymine and is hydrogen bonded to N<sub>1'</sub> of 2-aminopurine. This geometrical distortion is also accompanied by a rapid decrease in energy of the potential energy curve by  $\Delta E = 0.55$  eV (12.7 kcal mol<sup>-1</sup>) at the LEnergy<sub>min</sub> structure (Figure 15). As a consequence, it is not possible to form 2AP–T Tpl<sub>equi</sub> by migration of the (H)N<sub>3</sub> proton from thymine to 2-aminopurine.

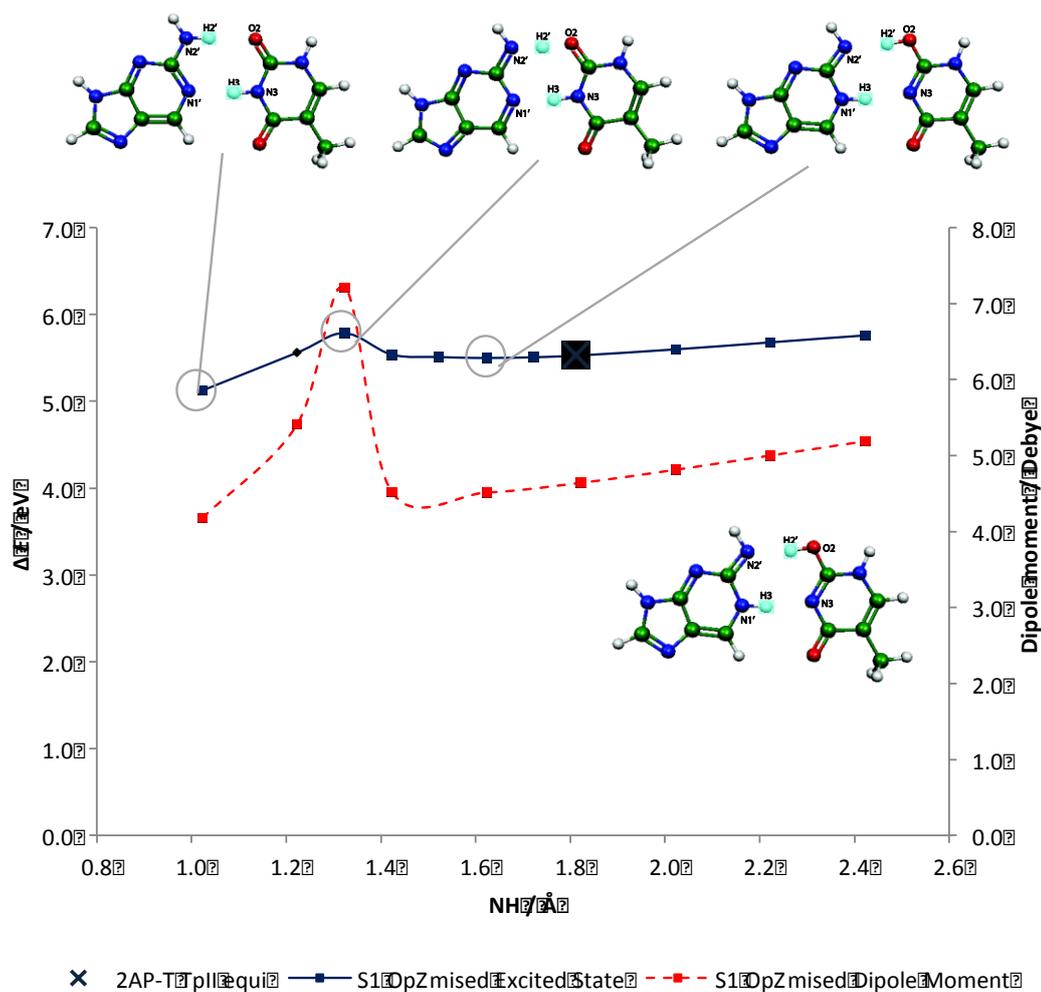

**Figure 15** Change in energy of the optimised ground state (S<sub>0</sub>) geometry as a function of H<sub>3</sub> to N<sub>3</sub> distance of the gas phase 2AP–T base pair for the proton transfer process N<sub>1'</sub>–(H)N<sub>3</sub>. Showing the 2AP–T Tpl<sub>equi</sub> structure, a local energy maximum (LEnergy<sub>max</sub>) of N<sub>2'</sub>(H) at 1.950 Å and finally a

rearrangement such that 2-aminopurine is in its original tautomeric form and thymine is in an alternative tautomeric form. An equilibrium structure for 2AP–T TplI could thus not be located.

### **2-Aminopurine-Thymine Proton Transfer Potential Energy Curves in excited electronic ground states**

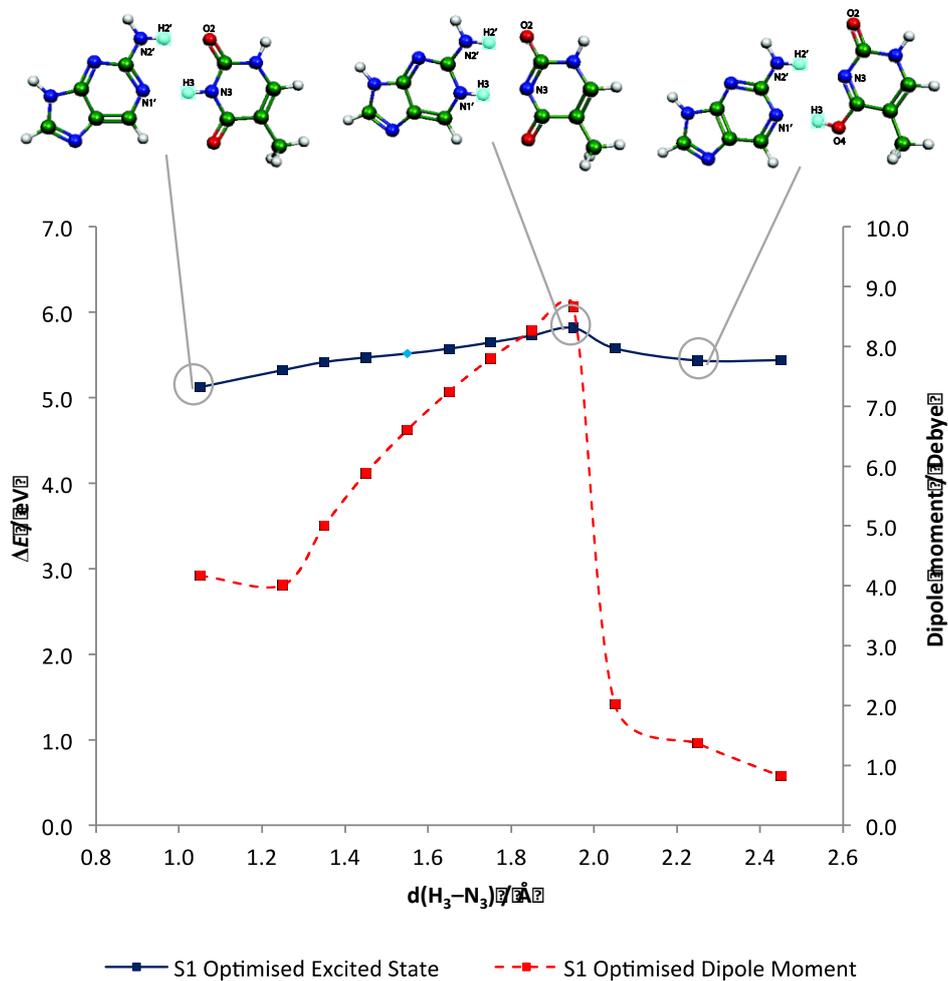

The potential energy curve of the optimised first excited state ( $S_1$ ) starting from 2AP–T Tpl<sub>equi</sub> with the migration of the  $N_2(H)$  proton from 2-aminopurine to thymine comprises, with one exception, of  ${}^1LE(\pi\pi^*)$  transitions on 2-aminopurine (Figure 16). There is a local energy maximum at  $(H)N_2 = 1.343$  Å, that is  $\Delta E = 0.66$  eV ( $15.2$  kcal mol<sup>-1</sup>) above the  $S_1$  2AP–T Tpl<sub>equi</sub> structure. There is also a reduction in hydrogen bond distances between the 2AP–T base pairs at the LEnergy<sub>max</sub> structure (middle base pair of top row Figure 16).

**Figure 16** Change in energy and dipole moment of the gas phase optimised geometry for the first electronic excited state of the 2AP–T base pair for the proton transfer process  $\text{N}_2(\text{H})\text{--O}_2$ . Showing the structure of 2AP–T  $\text{Tpl}_{\text{equi}}$ , the local energy maximum structure of  $\text{N}_2(\text{H})$  at  $1.323\text{\AA}$  and 2AP–T  $\text{Tpl}_{\text{equi}}$  at  $\text{N}_2(\text{H}) = 1.812\text{\AA}$  produced by unrestricted geometry optimisation (X on potential energy curve) is shown as an inset figure on the plot. The symbols  $\blacklozenge$  represents a state with some charge transfer character, ( $\pi_{2\text{AP}}\pi^*_\text{T}$ ).

Transfer of a second proton ( $H_3$ ) from thymine to 2-aminopurine results in the formation of a  $LEnergy_{min}$  structure at  $(H)N_2 = 1.623 \text{ \AA}$  (Figure 16). There is a decrease in both the energy ( $\Delta E = 0.25 \text{ eV}$  or  $5.8 \text{ kcal mol}^{-1}$ ) and dipole moment ( $\Delta \mu = 2.7 \text{ D}$ ) from the  $S_1$  optimised  $LEnergy_{max}$  to the  $S_1$  optimised  $LEnergy_{min}$  structures. The optimised  $S_1$   $LEnergy_{min}$  structure is higher in energy ( $\Delta E = 0.38 \text{ eV}$  or  $8.8 \text{ kcal mol}^{-1}$ ) than the  $S_1$  optimised 2AP-T  $TpI_{equi}$  structure. The geometry optimised structure of 2AP-T  $TpI_{equi}$  in its first electronically excited state ( $S_1$ ) was found by the optimisation of the  $S_1$   $LEnergy_{min}$  structure at CIS level without applying a geometry constraint.

The form of the potential energy curve of the  $S_1$  optimised geometry as a function of  $H_3-N_3$  distance (Figure 17) closely follows the shape of the  $S_0$  ground state, with a local energy maximum found at  $(H)N_3 = 1.950 \text{ \AA}$  which is  $0.69 \text{ eV}$  ( $15.9 \text{ kcal mol}^{-1}$ ) above the  $S_1$  optimised 2AP-T  $TpI_{equi}$  structure. The dipole moment of the  $S_1$  optimised geometries form a similar curve to that of the  $S_0$  ground state (Figure 15), reaching a local maximum ( $\mu = 8.7 \text{ D}$ ) at  $(H)N_3 = 1.950 \text{ \AA}$  (Figure 17).

**Figure 17** Change in energy and dipole moment of the optimised geometry of the gas phase for the first electronic excited state ( $S_1$ ) of the 2AP-T base pair for the proton transfer process  $\text{N}_1-(\text{H})\text{N}_3$ . Showing the 2AP-T  $\text{Tpl}_{\text{equi}}$  structure of 2AP-T and the single proton transfer structure at  $(\text{H})\text{N}_3$  1.950 Å. The  $\blacklozenge$  represents a state with some charge transfer character,  $\pi_{2\text{AP}}\pi_{\text{T}}^*$ .

### Possible conversion pathways between 2AP–T Tpl and 2AP–T TplI

Conversion from 2AP–T Tpl to 2AP–T TplI in neither the ground nor first electronically excited state is likely. In the ground state only 2AP–T Tpl was found to be stable. In the first excited state, although 2AP–T TplI could be optimized to yield a minimum energy structure in this tautomeric form, the structure is less stable than 2AP–T Tpl in the first excited state and there is insufficient energy in the  $S_0 \rightarrow S_1$  vertical transition at the 2AP–T Tpl<sub>equi</sub> structure to surmount the  $S_1$  optimised potential energy barrier at  $N_2(H) = 1.323 \text{ \AA}$  and form 2AP–T TplI in the excited state.

## CONCLUSION

Three base pair tautomers of PC–G were studied. In the electronic ground state the lowest energy tautomer pair was found to be PC–G Tpl<sub>equi</sub>, which is analogous to the lowest energy tautomer pair of C–G. A second tautomer pair, PC–G TplI<sub>equi</sub> was found but was less thermodynamically stable than PC–G Tpl<sub>equi</sub> in the ground electronic state. A third structure, PC–G TplIII<sub>equi</sub>, was not found to be stable in the ground electronic state. In the first electronically excited state however, PC–G TplI<sub>equi</sub> was found to be more stable than PC–G Tpl<sub>equi</sub>. It is suggested that excitation of PC–G Tpl<sub>equi</sub> to the first electronically excited state could lead to the formation, via double proton transfer, of electronically excited PC–G TplI<sub>equi</sub>, which would return to the ground electronic state, forming ground state PC–G TplI<sub>equi</sub>. Thus an excited state double proton transfer reaction could provide an alternative route for electronically excited pyrrolocytosine to return to the electronic ground state when in a base paired environment, and thus may be responsible for the different fluorescence properties of pyrrolocytosine in hydrogen bonded environments, compared to when not hydrogen bonded.

In the case of the 2-aminopurine-thymine base pair, only one tautomer 2AP–T Tpl<sub>equi</sub>, which is analogous to the A–T structure, was found to be stable in the ground electronic state. In the first electronically excited state a second tautomer pair structure was found to be stable, 2AP–T Tpl<sub>II</sub> but this structure is less stable than the 2AP–T Tpl<sub>equi</sub> in the first excited state, and excitation of 2AP–T Tpl<sub>equi</sub> to the first excited state is not expected to lead to the formation of 2AP–T Tpl<sub>II</sub> in the excited state.

In summary, the potential energy curves found in this work have enabled the identification of stable ground state ( $S_0$ ) and first electronic excited state ( $S_1$ ) base pair tautomers for PC–G and 2AP–T and suggest, in the case of PC–G, that excited state conversion of tautomeric forms may occur, allowing potentially for alternative decay pathways when PC is in a hydrogen bonded environment with guanine.
